1 Language recognition with an RNN

If you've ever used an online translator you've probably seen a feature that automatically detects the input language. While this might be easy to do if you input unicode characters that are unique to one or a small group of languages (like “ ” or “ ”), this problem is more challenging if the input only uses the available ASCII characters. In this case, something like “těší mě” would become “tesi me” in the ascii form. This is a more challenging problem in which the language must be recognized purely by the pattern of characters rather than unique unicode characters.

We will train an RNN to solve this problem for a small set of languages that can be converted to romanized ASCII form. For training data it would be ideal to have a large and varied dataset in different language styles. However, it is easy to find copies of the Bible which is a large text translated to different languages but in the same easily parsable format, so we will use 20 different copies of the Bible as training data. Using the same book for all of the different languages will hopefully prevent minor overfitting that might arise if we used different books for each language (fitting to common characteristics of the individual books rather than the language).

```
[3]: from unicode import unicode as unicodeToAscii

all_characters = string.printable
n_letters = len(all_characters)
```

```
print(unicodeToAscii('těší mě'))
```

tesi me

```
[4]: # Read a file and split into lines
def readFile(filename):
    data = open(filename, encoding='utf-8').read().strip()
    return unicodeToAscii(data)

def get_category_data(data_path):
    # Build the category_data dictionary, a list of names per language
    category_data = {}
    all_categories = []
    for filename in glob.glob(data_path):
        category = os.path.splitext(os.path.basename(filename))[0].split('_')[0]
        all_categories.append(category)
        data = readFile(filename)
        category_data[category] = data

    return category_data, all_categories
```

The original text is split into two parts, train and test, so that we can make sure that the model is not simply memorizing the train data.

```
[5]: train_data_path = 'language_data/train/*_train.txt'
test_data_path = 'language_data/test/*_test.txt'

train_category_data, all_categories = get_category_data(train_data_path)
test_category_data, test_all_categories = get_category_data(test_data_path)

n_languages = len(all_categories)

print(len(all_categories))
print(all_categories)
```

20

```
['english', 'esperanto', 'albanian', 'finnish', 'spanish', 'italian',
'lithuanian', 'french', 'maori', 'romanian', 'german', 'portuguese', 'turkish',
'swedish', 'hungarian', 'czech', 'vietnamese', 'xhosa', 'danish', 'norwegian']
```

2 Data processing

```
[6]: def categoryFromOutput(output):
    top_n, top_i = output.topk(1, dim=1)
    category_i = top_i[:, 0]
    return category_i
```

```

# Turn string into long tensor
def stringToTensor(string):
    tensor = torch.zeros(len(string), requires_grad=True).long()
    for c in range(len(string)):
        tensor[c] = all_characters.index(string[c])
    return tensor

def load_random_batch(text, chunk_len, batch_size):
    input_data = torch.zeros(batch_size, chunk_len).long().to(device)
    target = torch.zeros(batch_size, 1).long().to(device)
    input_text = []
    for i in range(batch_size):
        category = all_categories[random.randint(0, len(all_categories) - 1)]
        line_start = random.randint(0, len(text[category]) - chunk_len)
        category_tensor = torch.tensor([all_categories.index(category)],
→dtype=torch.long)
        line = text[category][line_start:line_start+chunk_len]
        input_text.append(line)
        input_data[i] = stringToTensor(line)
        target[i] = category_tensor
    return input_data, target, input_text

```

3 Implement Model

For this classification task, we can use the same model we implement for the generation task which is located in `rnn/model.py`. See the `MP4_P2_generation.ipynb` notebook for more instructions. In this case each output vector of our RNN will have the dimension of the number of possible languages (i.e. `n_languages`). We will use this vector to predict a distribution over the languages.

In the generation task, we used the output of the RNN at every time step to predict the next letter and our loss included the output from each of these predictions. However, in this task we use the output of the RNN at the end of the sequence to predict the language, so our loss function will use only the predicted output from the last time step.

4 Train RNN

```
[7]: from rnn.model import RNN
```

```
[8]: chunk_len = 50

BATCH_SIZE = 100
n_epochs = 10000
hidden_size = 160
n_layers = 3
learning_rate = 0.0001
```

```

model_type = 'lstm'

criterion = nn.CrossEntropyLoss()
rnn = RNN(n_letters, hidden_size, n_languages, model_type=model_type,
    ↪n_layers=n_layers).to(device)

```

TODO: Fill in the train function. You should initialize a hidden layer representation using your RNN's `init_hidden` function, set the model gradients to zero, and loop over each time step (character) in the input tensor. For each time step compute the output of the of the RNN and the next hidden layer representation. The cross entropy loss should be computed over the last RNN output scores from the end of the sequence and the target classification tensor. Lastly, call backward on the loss and take an optimizer step.

```

[9]: def train(rnn, target_tensor, data_tensor, optimizer, criterion,
    ↪batch_size=BATCH_SIZE):
    """

4.1 Plot loss functions

```
[12]: import matplotlib.pyplot as plt
import matplotlib.ticker as ticker

plt.figure()
plt.plot(all_losses, color='b')
plt.plot(all_test_losses, color='r')
```

```
[12]: [<matplotlib.lines.Line2D at 0x2b488b358f10>]
```

4.2 Evaluate results

We now visualize the performance of our model by creating a confusion matrix. The ground truth languages of samples are represented by rows in the matrix while the predicted languages are represented by columns.

In this evaluation we consider sequences of variable sizes rather than the fixed length sequences we used for training.

```
[13]: eval_batch_size = 1  # needs to be set to 1 for evaluating different sequence
      ↪ lengths

      # Keep track of correct guesses in a confusion matrix
      confusion = torch.zeros(n_languages, n_languages)
      n_confusion = 1000
      num_correct = 0
```

```

total = 0

for i in range(n_confusion):
    eval_chunk_len = random.randint(10, 50) # in evaluation we will look at
    ↪ sequences of variable sizes
    input_data, target_category, text_data =
    ↪ load_random_batch(test_category_data, chunk_len=eval_chunk_len,
    ↪ batch_size=eval_batch_size)
    output = evaluate(rnn, input_data, seq_len=eval_chunk_len,
    ↪ batch_size=eval_batch_size)

    guess_i = categoryFromOutput(output)
    category_i = [int(target_category[idx]) for idx in
    ↪ range(len(target_category))]
    for j in range(eval_batch_size):
        category = all_categories[category_i[j]]
        confusion[category_i[j]][guess_i[j]] += 1
        num_correct += int(guess_i[j]==category_i[j])
    total += 1

print('Test accuracy: ', float(num_correct)/float(n_confusion*eval_batch_size))

# Normalize by dividing every row by its sum
for i in range(n_languages):
    confusion[i] = confusion[i] / confusion[i].sum()

# Set up plot
fig = plt.figure()
ax = fig.add_subplot(111)
cax = ax.matshow(confusion.numpy())
fig.colorbar(cax)

# Set up axes
ax.set_xticklabels([''] + all_categories, rotation=90)
ax.set_yticklabels([''] + all_categories)

# Force label at every tick
ax.xaxis.set_major_locator(ticker.MultipleLocator(1))
ax.yaxis.set_major_locator(ticker.MultipleLocator(1))

plt.show()

```

Test accuracy: 0.928

You can pick out bright spots off the main axis that show which languages it guesses incorrectly.

4.3 Run on User Input

Now you can test your model on your own input.

```
[14]: def predict(input_line, n_predictions=5):
    print('\n> %s' % input_line)
    with torch.no_grad():
        input_data = stringToTensor(input_line).long().unsqueeze(0).to(device)
        output = evaluate(rnn, input_data, seq_len=len(input_line),
        ↪batch_size=1)

    # Get top N categories
    topv, topi = output.topk(n_predictions, dim=1)
    predictions = []

    for i in range(n_predictions):
        topv.shape
        topi.shape
        value = topv[0][i].item()
        category_index = topi[0][i].item()
```

```

        print('({:.2f}) {}'.format(value, all_categories[category_index]))
        predictions.append([value, all_categories[category_index]])

predict('This is a phrase to test the model on user input')

```

```

> This is a phrase to test the model on user input
(14.20) english
(2.62) albanian
(2.38) spanish
(1.72) french
(1.72) german

```

5 Output Kaggle submission file

Once you have found a good set of hyperparameters submit the output of your model on the Kaggle test file.

```

[15]: ### DO NOT CHANGE KAGGLE SUBMISSION CODE ###
import csv

kaggle_test_file_path = 'language_data/kaggle_rnn_language_classification_test.
↳txt'
with open(kaggle_test_file_path, 'r') as f:
    lines = f.readlines()

output_rows = []
for i, line in enumerate(lines):
    sample = line.rstrip()
    sample_chunk_len = len(sample)
    input_data = stringToTensor(sample).unsqueeze(0)
    output = evaluate(rnn, input_data, seq_len=sample_chunk_len, batch_size=1)
    guess_i = categoryFromOutput(output)
    output_rows.append((str(i+1), all_categories[guess_i]))

submission_file_path = 'kaggle_rnn_submission.txt'
with open(submission_file_path, 'w') as f:
    output_rows = [('id', 'category')] + output_rows
    writer = csv.writer(f)
    writer.writerows(output_rows)

```

```
[ ]:
```
